ABSTRACT.—The Short-toed Eagle (Circaetus gallicus) uses mainly soaring flight during migration and avoids long water crossings between Italy and Africa by crossing at the Strait of Gibraltar. Observations were made 15–26 September 2000 at four sites in the central Mediterranean area: Arenzano (Ligurian Apennines, northwest Italy), Circeo (Province of Latina, central Italy), Maretimino (northeast Italy) and Malta. In addition, 68 hr of observations were made 18–24 September 1998, 1999, and 2000 over the Apuan Alps along the western slope of central Italy. At Arenzano, 456 Short-toed Eagles were counted (5.4/hr) consisting of 286 adults, 6 immatures, and 192 juveniles, with an overlap in the migration periods of age classes. The Short-toed Eagles migrated in flocks averaging 4.3 ± 0.9 (SE) birds. Over the Apuan Alps, 288 Short-toed Eagles, all migrating northwest, were counted (4.5/hr). Few birds were seen at the other three sites, with a maximum of eight individuals recorded at Maretimino. These results confirm the circuitous autumn migration around the Mediterranean of Short-toed Eagles breeding in central Italy and suggest that at least some juveniles learn this route by following the adults.

KEY WORDS: Short-toed Eagle; Circaetus gallicus; migration; orientation; flocking; navigation.

Circuitu de migración de otoño de Circaetus gallicus

RESUMEN.—Circaetus gallicus usa principalmente el vuelo de planee durante la migración y evita los largos cruces sobre el agua entre Italia y África cruzando por el estrecho de Gibraltar. Se hicieron observaciones entre 15–26 de septiembre de 2000 en cuatro sitios en el área mediterránea central: Arenzano (Apennines Ligurian, norte de Italia), Circeo (Italia central), Maretimino (sur de Italia) y Malta. Además, 68 horas de observaciones fueron entre 18–24 de septiembre de 1998, 1999, y 2000 sobre los Alpes de Apuanas, a lo largo de la vertiente este de Italia central. En Arenzano, 476 águilas de pies cortos fueron contadas (5.4/hr) incluyendo 286 adultos, 6 inmaduros, y 192 juveniles, con un tránsito en los periodos de migración de edades. Las águilas de pies cortos migran en bandadas que promedian 4.3 ± 0.9 (SE) aves. Sobre los Alpes de Apuanas, fueron contadas 288 Circaetus gallicus (4.5/hr), todas emigrantes del noreste. pocas aves fueron vistas en los otros tres sitios, con un máximo de ocho individuos registrados en Maretimino. Estos resultados confirman el circuito migratorio de otoño alrededor del mediterráneo de Circaetus gallicus que aprenden en Italia central y sugiere que al menos algunos juveniles aprenden esta ruta siguiendo los adultos.

[Traducción de César Márquez]

The Short-toed Eagle (Circaetus gallicus) is a summer resident in Europe, wintering in tropical North Africa (Cramp and Simmons 1980). It has a breeding population of 380–415 pairs, most of them in the Ligurian Apennines (northwest Italy) and along the western slope of central Italy (Cataneo and Petrelli 1992: Fig. 1). A small number of pairs breed in southern continental Italy and

probably winter in Sicily (Mascara 1985, Cattaneo and Petretti 1992, Cattaneo 1997, Agostini and Logozzo 1997). In the Mediterranean basin, the greatest concentration of individuals has been observed at the Strait of Gibraltar both during autumn and spring movements (Finlayson 1992).

Information in support of a circumpolar migration route for Short-toed Eagles has been circumstantial to date. In the central Mediterranean, passage of these birds is virtually non-existent during spring (Beaman and Galea 1974, Agostini and Malara 1997, Agostini and Logozzo 1998; Agostini 1990). Individuals breeding in both northern and central Italy are expected to cross the Mediterranean at the Strait of Gibraltar, traveling along the Ligurian Apennines (northwest Italy, Agostini and Malara 1997), where their greatest concentration in Italy occurs during spring migration (Baghino and Leugio 1989, 1990).

Baghino 1996). In autumn, a few birds are recorded in southern continental Italy and over the islands of Malta and Capri (Beaman and Galea 1974, Sultana and Gucci 1982, Agostini and Logozzo 1996a, 1995b, 1997, Jørgen and Pettersson 1999), although over Malta, Short-toed Eagles are occasionally recorded in November (Coleiro 1999). These results suggested the hypothesis that Short-toed Eagles breeding in central Italy avoid the long water crossing between Italy and Africa and that they move across the Mediterranean at the Strait of Gibraltar rather than via southern Italy (Agostini and Logozzo 1997). Because this route involves circuitous migration (Fig. 1), it suggests information transmission and, thus, a contemporaneous migration of adults (experienced individuals) and juveniles (inexperienced individuals). The aim of this study was to verify these hypotheses through observations at five sites of the central Mediterranean: the Ligurian Apennines, the Apuan Alps (central Italy), the Circeo promontory (central Italy), the islands of Marettimo (western Sicily, southern Italy) and Malta. At the last three sites, remarkable concentrations of raptors occur in autumn (Beaman and Galea 1974, Cochi et al. 1999, Agostini et al. 2000), while, to date, on the Ligurian Apennines and on the Apuan Alps observations of migrating individuals in this period were lacking.

STUDY AREA AND METHODS

With the exception of those observations made in the Apuan Alps, we collected our data from 15-20 September 2000, the peak of the autumn migration of the Short-toed Eagle in the Mediterranean basin (Gramp and Simmons 1980). The entire observation period was divided into four 3-d periods for recording the migration of adult, immature, and juvenile individuals. Observations were aided with binoculars and telescopes. Age determination was possible only when the birds flew very close (<150 m) overhead. An estimated total of adults, immatures, and juveniles was derived by multiplying their proportions in the sample of identified individuals during each period, following the method used by Kjellén (1992) in his study on the autumn migration of raptors at the Falsterbo peninsula (Sweden). Characters used in separating age were those given by Forsman (1999).

In the Ligurian Apennines, the observation post was at the northernmost point of the midwestern Mediterranean basin, near Arenzano (Fig. 1), where the ridge of Apennines, after running parallel to the coast, reaches its closest proximity to the sea (6 km) as well as the minimum transverse width for the entire Italian peninsula. The observation post was on the closest culmination to the sea at 500 m aal.

The Circeo promontory is at the southernmost point of the Pianura Ponente (Fig. 1) reaching 541 m aal. In autumn 1998, hundreds of Marsh Harriers (Circus aeruginosus) and juvenile Honey Buzzards (Pernis apivorus)
Figure 2. Occurrence of migrating Short-toed Eagles in the Ligurian Apennines between 15-26 September 2000.

were seen leaving the coast toward the island of Favigna from this point (Corbí et al. 1999, Fig. 1), but only five Short-toed Eagles. The observation post was along the southern slope nearly at its highest point.

Marettimo is a small mountainous island (12 km²) about 30 km off western Sicily (Fig. 1). Monte Falcone is its highest relief at 686 m. At this site, observations were made between the end of August and the first half of September 1997 and 1998 when a maximum of 5267 rap- tors were counted, nearly all Black Kites (Milvus migrans) and adult Honey Buzzards; only one Short-toed Eagle was reported in 1997 (Agostini et al. 2000). To date no ob- servations have been carried out after mid-September. The observation post was located at the altitude of ca. 500 m.

The Maltese Islands are ca. 90 km south of Sicily and 335 km north of Libya (Fig. 1). Raptors, mostly Marsh Harriers and juvenile Honey Buzzards (Aguistì and Lo- guzzo 1995c), concentrate along the cliffs (Breaman and Gaeta 1974). The observation post was on the western side of the island of Malta, at one of the highest points of the island (250 msl). At the Ligurian Apennines and in the Circeo promontory, no monitoring was done on 26 September because of heavy rainfalls.

At the Apuan Alps site, observations were made between 18-24 September 1999 (16 hr), 1999 (20 hr), and 2000 (32 hr). The observation post was located on the slope of Mount Cologno, about 370 km NW of the Circeo promontory and 130 km SE of Azzara (Fig. 1), at the altitude of ca. 300 m. This site was used to detect the direction of Short-toed Eagles migrating along the west- ern slope of central Italy.

RESULTS AND DISCUSSION

On the Ligurian Apennines (Azzara), we counted a total of 176 Short-toed Eagles (5.4/hr) with about 55% of birds seen in two days (Fig. 2). This species was the most abundant at this site (79.6%, N = 589). During the four 3-day periods, a total of 868 adults, six immatures, and 102 juve- niles were estimated, with an overlap in the migra- tion periods of individuals belonging to different age classes (Fig. 3). The Short-toed Eagles showed a strong tendency to migrate in flocks of two or more (N = 96), although 62 (13.1%) individuals were seen alone. On average, groups consisted of 4.3 ± 0.9 (SE) individuals and 64% (61 of 96) of flocks contained two or three birds. It was possible to age all birds migrating together in 23 (24%) cases, seven of these groups consisted of juveniles and adults while 16 comprised only adults. In at least four of the remaining 73 flocks recorded, ju- veniles and adults were seen migrating together. Few Short-toed Eagles were counted at the other three sites. However, three birds were seen on the Circeo promontory (0.4%, N = 832), two over Mal- ta (0.2%, N = 357) and eight over Marettimo (2.8%, N = 286). Finally, over the Apuan Alps, a total of 289 Short-toed Eagles were counted (4.5/ hr), and all individuals were seen migrating north- west toward the Ligurian Apennines (Fig. 1).

Our observations are consistent with the predic- tions based on the circuitous migration hypothesis. During autumn migration, Short-toed Eagles breeding in central Italy migrate over the Ligurian Apennines en route to the Strait of Gibraltar, thus avoiding a longer sea crossing between Italy and Africa. Flights suggestive of circuitous migration during autumn have been recorded in genera such as Hirundo and Motacilla (Alerstam 1990) and, among raptors, in Griffon Vultures (Gyps fulvus) breeding in the island of Cerès (Croatia: Suic, in Zalles and Bildstein 2000, p. 220). Along the coast- al zone in southern Sweden, many birds are seen regularly migrating north or northeast. However, these movements seem to be made in order to find suitable stop-over sites inland before crossing the sea (Alerstam 1990) and they are not the result of a true migration movement. In the case of our study, both the strong tendency of Short-toed Eagles to migrate together and flocks containing in-
dividuals belonging to different age classes, are consistent with the prediction that at least some juveniles belonging to the population breeding in central Italy are able to learn this circumpatral route by following the adults (Agostini and Logozzo 1997). Before this study, among migrating raptors, information transmission concerning orientation and navigation has been recorded in Black Kites and, occasionally, Honey Buzzards migrating across the central Mediterranean (Agostini and Logozzo 1997; Agostini et al. 1999, 2006).

ACKNOWLEDGMENTS

This research was partially supported through the activities of the Stazione di Frangeolamento di Palermo, funded by the Assessamento Agricola e Forestale of the Regione Siciliana. Moreover, this study was endorsed by the Provincia di Geroa. We wish to thank Giuseppe Di Lieto, Fabio Finos, and Michele Panuccio for their help during observations at the Cireco promontory. Our particular gratitude goes to Bruno Mava, Paul Reijvenga, Keith Bildstein, Nila Kjellen, and Ian Warkentin for their useful comments on earlier drafts of the manuscript.
